and many many others...**

The ISM in galaxies

The ISM is violent and multiphase

- hot ionized gas
- HII regions
- dense molecular clouds
- diffuse ionized gas
- warm neutral gas
- cool neutral gas

Contain the bulk of the ISM in normal star-forming galaxies. Heating and cooling mechanism are the more complex...

Heating and cooling in the ISM

A new exciting window on the ISM: spectroscopy in the FIR/sub-mm region.

- Contains diagnostic lines from the ionized, neutral and molecular ISM (including the lines that are dominate the cooling of the ISM)
- Continuum emission from cold dust

Problem: FIR/sub-mm observations are not easy to do...

Only low-J transitions of important molecules (CO, HCN...) can be done from the ground.

Important FIR/submm lines

[CII] 158 μm

[OI] 63 μm

[OI] 145 μm

[CI] 370 μm

[CI] 609 μm

Fine-structure lines of neutral atoms (and C^+ which has an ionization energy $< 13.6 \text{ eV}$). Most important cooling lines of the neutral ISM

[NII] 122 μm

[NII] 205 μm

[NIII] 57 μm

[OIII] 52 μm

[OIII] 88 μm

Fine-structure lines of ionized atoms. Important lines to probe the conditions in the ionized ISM (linked to SF or AGN).

CO

OH sub-mm

H_2O and mm

HCN

Many lines corresponding to rotational transitions in molecules. Ideal to probe the conditions in the molecular ISM.

....

Observing the cold ISM in galaxies

Options for FIR/sub-mm spectroscopy have been very modest

- IRAS: only continuum
- KAO FIFI: FIR up to $200\ \mu\text{m}$
- ISO LWS: FIR up to $200\ \mu\text{m}$
- Spitzer IRS: only up to $38\ \mu\text{m}$
- SOFIA: coming soon...

KAO (1974-1995)
92 cm

SOFIA (2011-)
2.5 m

ISO (1995-1998)
60 cm

Herschel Space Observatory

Fourth cornerstone mission of ESA's
Cosmic Vision 2005-2015
Contribution from NASA and CSA

Launched 14 May 2009, together with
Planck

Main strengths of Herschel

- Large, passively cooled, 3.5 m mirror
- Wavelength coverage to sub-mm wavelengths
- Position in L_2

Herschel instruments

Photodetector Array Camera and Spectrometer (PACS)

- imaging at 70, 100 and 160 μm
- integral-field spectroscopy (55-105 μm , 105-210 μm)
- resolution: 1000-5000

Spectral and Photometric Imaging Receiver (SPIRE)

- imaging at 250, 350 and 500 μm
- imaging Fourier Transform spectrometer (194-672 μm)
- resolution: 40-1000 at 250 μm

Heterodyne Instrument for the Far Infrared (HIFI)

- seven-beam high-resolution spectrometer (157-625 μm)
- resolution: up to 10^7

Herschel first light...

Fritz et al. 2011, in preparation

Very Nearby Galaxies Survey (VNG)

Detailed study of 13 large, prototypical galaxies

- deep PACS and SPIRE images
- PACS spectroscopy in several lines
- SPIRE FTS spectroscopy in the nucleus

- PACS spectroscopy in several lines
- SPIRE FTS spectroscopy in the nucleus

Most of the imaging data available

Some FTS and PACS spectroscopy already available...

PACS and SPIRE

Interstellar dust in M81

Science Demonstration
Phase observations of
M81:
spectacular improvement
of resolution compared to
Spitzer

Bendo et al. 2010

250/350 and 350/500 ratios
correlate with radius but not
with surface brightness

160-500 μm emission traces
15-30 K dust heated by evolved
stars in the bulge and disc.
70 μm traces dust heated by
star forming regions and AGN.

Interstellar dust in the M81 group

Diffuse FIR emission in the M81 group
– often considered to be intra-group material.

Striking correlation between Herschel data and THINGS HI data in a very narrow frequency range (2-3 km/s). Suggests a Galactic cirrus origin for the diffuse FIR emission.

M82

M82

Nearest (3.4 Mpc) powerful starburst galaxy with galactic fountain (outflowing ionized gas). Atomic lines prominent in ISO LWS spectrum.

Remarkable feature in Spitzer IRS spectrum: prominent H₂ rotational lines indicate substantial amount of warm molecular gas...

Colbert et al. 1999

Beirão et al. 2008

SPIRE observations of M82

SPIRE imaging reveals strong dust emission in the halo and tidal streams. Direct proof of efficient enrichment of the ICM with metals.

Roussel et al. 2010

SPIRE spectroscopy of central 43'': detects mainly lines of CO and ^{13}CO .

Combination of SPIRE spectroscopy and ground-based spectroscopy: continuous CO ladder from J=1-0 to J=13-12

Panuzzo et al. 2010

CO ladder in M82

NLTE radiative transfer modelling: proves the existence of warm 500 K molecular gas in M82, next to the cold component (25 K) detected at low J .

At these temperatures, MIR H_2 lines (and not CO or [CII] lines) are the dominant coolant of the ISM. In agreement with Spitzer IRS spectrum.

Dominant heating mechanism of the warm CO gas: mechanical heating from stellar winds and supernovae (UV-powered PDR, X-ray powered XDR and cosmic rays are excluded).

Arp 220

HUBBLE SPACE TELESCOPE VIEW

GROUND VIEW

Arp 220

Nearest (77 Mpc) ULIRG with $L_{\text{FIR}} \approx 10^{12} L_{\odot}$.
Contains 2 merging nuclei and a completely optically thick merger-induced star formation burst.

Huge reservoir of molecular gas available (about $10^{10} M_{\odot}$). FIR spectrum (ISO LWS) very different from M82 spectrum: many emission and absorption lines of molecules (OH, H₂O, NH, NH₃...)

Important unresolved question: does Arp 220 host an AGN (important as Arp 220 is often used as template for high-z galaxies)

Gonzalez-Alfonso et al. 2004

SPIRE spectroscopy of Arp 220

Deep SPIRE FTS spectrum (200-670 μm)
with very good calibration (5%) and an
impressive set of lines.

Emission lines of atoms (C I and [N II]) and molecules (CO, H₂O...). Impressive: total luminosity in H₂O similar to luminosity in CO lines: cooling by water is very important !

Also many molecular lines in absorption. Very prominent absorption lines from hybrids (H_2O^+ , CH^+ , OH^+). Their abundances support the presence of a hidden AGN.

CO ladder in Arp 220

Similar approach as for M82:
NLTE radiative transfer modelling
of CO ladder (combination of
ground-based and SPIRE lines).

CO SLED can only be explained by
combination of cold (50 K) and
warm (1350 K) gas. Warm CO
component contains only 10% of
mass, but dominates the
luminosity and the cooling.

Heating mechanism similar as for
M82: XDR, PDR and cosmic rays
are improbable, mechanical
heating remains possibility.

HCN ladder in Arp 220

HCN can be a very good tracer for dense molecular gas (rotational transitions have critical densities 100-1000 times those of CO).

Low-J transitions detected from the ground, high-J transitions in absorption by SPIRE.

NLTE HCN ladder modelling: evidence for “infrared pumping mechanism” of photons at 14 μm. Requires an intense radiation field with T>350 K.

A molecular outflow in Arp 220

Remarkable line shapes of OH⁺, H₂O⁺ and HF lines: P Cygni profiles.

Strong signature of outflow activity.
Direct evidence of feedback mechanism (very important ingredient in galaxy evolution studies).

Unfortunately, lines are not well resolved, so impossible to measure outflow velocity and outflow rate.
Herschel HIFI follow-up observations of selected lines are scheduled.

The Herschel ATLAS

Widest area survey with Herschel (550 deg²). Covers 5 bands with PACS and SPIRE (100-500 μm)

Consortium of 150+ astronomers worldwide, from galactic astronomers to cosmologists

Expected catalogue: about 10^5 sources, up to $z > 3$

Primary aim: provide the kind of leap in the FIR/sub-mm that 2dF/SDSS made in the optical

The Herschel ATLAS

Collaboration between H-ATLAS and GAMA consortia: redshifts and UV/optical/NIR imaging and spectra for many nearby (and distant) galaxies.

Gravitational lenses in H-ATLAS

Model predictions: strongly lensed sub-mm galaxies at high- z become a significant/dominant population at sub-mm wavelengths.

Extensive follow-up campaign of possible H-ATLAS 500 μm peakers: confirmation of high redshifts and lens nature of various sources.

Negrello et al. 2008

Frayer et al. 2010

Gravitational lenses in H-ATLAS

Negrello et al. 2010, Science

H-ATLAS lenses: an example

SDP.81 = sub-mm source at $z = 3.04$
Redshift determined from ground-based
CO spectroscopy.

Lensing nature confirmed using high-
resolution SMA observations.

Lens modelling (IRAC + Keck): lens is
foreground early-type galaxy at $z = 0.30$.

Hopwood et al. 2011

Physical conditions in high-z lenses

Unique targets for investigation of physical conditions in high-z galaxies (magnification factor typically 25) !

Follow-up spectroscopy program for high-z H-ATLAS lenses

- Ground-based observations: molecular lines (CO, H₂O)
- SPIRE FTS: atomic fine-structure lines

[CII] and [OIII] detected in SDP.81.

Modelling of physical conditions: extreme star-formation (UV radiation field 200 times the local Galactic ISRF)

Many more detections (and statistics) to be made in near future. The best is yet to come !

Summary

1. FIR/sub-mm domain is a fascinating region to study the physics of the ISM: both dust and (ionized, neutral and molecular) gas.
2. Herschel is fantastic (imaging and spectroscopy 70-670 μm) !
3. Very Nearby Galaxies Survey: detailed study of 13 prototypical galaxies.
Many fascinating photometry results, first spectroscopy results
 - Warm and dense molecular gas in M82 and Arp 220, probably heated by mechanical energy from starburst
 - Many molecular species (including hybrids) and strong molecular outflow in Arp 220
4. H-ATLAS: large-scale sub-mm survey with multi- follow-up programs. Sub-mm/mm spectroscopy of gravitationally lensed sub-mm galaxies offers unique possibility to study the ISM in high-z galaxies.

FIR/submm spectroscopy with Herschel: results from the VNG and H-ATLAS surveys

PACS fact sheet

Projection of focal plane onto spectrometer arrays

Integral Field Spectrometer

Simultaneous 55-105 & 105-210 μm spectroscopy.

47" x 47" (5x5 pixels) FOV rearranged via an image slicer on two 16x25 Ge:Ga detector arrays.

$$\lambda/\Delta\lambda \sim 1000-5000$$

Point source line sensitivity:
 $\sim 4-10 \times 10^{-18} \text{ W/m}^2$ (5σ , 1h)

PACS is one of three science instruments for ESA's Herschel mission. It operates either as an imaging photometer or an integral field spectrometer over the spectral band from 55 to 210 μm .

Projection of focal plane onto bolometer arrays

Imaging Photometer

Simultaneous two-band (same FOV) 60-85 μm or 85-130 and 130-210 μm fully sampled imaging.

Two filled bolometer arrays:
32x16 and 64x32 pixels

Point source detection limit:
 $\sim 3-5 \text{ mJy}$ (5σ , 1h)

PACS is being designed and built by a consortium of institutes and university departments from across Europe under the leadership of Principal Investigator Albrecht Poglitsch located at Max-Planck-Institute for Extraterrestrial Physics, Garching, Germany. Consortium members are: Austria: UVIE; Belgium: IMEC, KUL, CSL; France: CEA, OAMP; Germany: MPE, MPIA; Italy: IFSI, OAP/OAT, OAA/CAISMI, LENS, SISSA; Spain: IAC.

SPIRE fact sheet

Imaging Photometer

Simultaneous observation in 3 bands
139, 88, and 43 pixels
Wavelengths: 250, 350, 500 μm
 $\lambda/\Delta\lambda \sim 3$
FOV 4' x 8', beams 18'', 25'', 36''

Estimated Photometer Sensitivities

Wavelengths (μm)	250	350	500
Point Source (mJy, 7-point mode)	1.8	2.2	1.7
Small map (mJy, 5 σ , 1hr)	6.2	8.4	7.1
Large map (mJy, 5 σ , 1hr)	3.7	5.3	4.6

General
Beam Steering Mirror
T= 0.3 K by ^3He sorption cooler
Hexagonal Spider-web bolometer arrays

Estimated Spectrometer Sensitivities

Wavelengths (μm)	200-315	315-500	500-670
Point Source ($10^{-17} \text{ W m}^{-2}$, 5 σ , 1hr, res 0.04 cm^{-1})	2.5-4	2-3	3-4
2.6' map ($10^{-17} \text{ W m}^{-2}$, 5 σ , 1hr, res 0.04 cm^{-1})	~15	~10	~15
Point Source (mJy, 5 σ , 1hr, res 1 cm^{-1})	85-125	70-110	110-130
2.6' map (mJy, 5 σ , 1hr, res 1 cm^{-1})	~500	~400	~500

Imaging Fourier Transform Spectrometer

Simultaneous imaging observation of the whole spectral band
37 and 19 pixels
Wavelength range: 194-672 μm
 $\lambda/\Delta\lambda = 40, 160, \text{ or } 1000 \text{ at } 250 \mu\text{m}$
FOV 2.6' circular, beams 16'', 34''

The SPIRE Consortium: SPIRE is being designed and built by a consortium of institutes and university departments from across Europe, Canada and the USA, under the leadership of a Principle Investigator (Professor M.J. Griffin) located at the University of Wales, Cardiff. The member institutes are: Astronomy Technology Centre (ATC), Edinburgh; Observatoire de Meudon (DESPA), Paris; CEA, Service des Basses Températures (SBT), Grenoble; Goddard Space Flight Center (GSFC), Maryland; Instituto de Astrofísica de Canarias (IAC), Tenerife; Institut d'Astrophysique Spatiale (IAS), Orsay; Imperial College London; Instituto di Fisica dello Spazio Interplanetario (IFSI), Rome; Jet Propulsion Laboratory (JPL), Pasadena; Laboratoire de Marseille (LAM), Marseille; Mullard Space Science Laboratory (MSSL), Holmbury St. Mary; Padova Observatory, Padova; University of Wales, Cardiff; Rutherford Appleton Laboratory (RAL), Chilton; CEA, Service d'Astrophysique (Sap), Saclay; University of Lethbridge, Canada; Stockholm Observatory, Sweden

(version July 2007)

HIFI fact sheet

Principal Investigator: Thijs de Graauw, SRON, Groningen, The Netherlands
Co-PIs: Tom Phillips, Caltech; Emmanuel Caux, CESR; Jürgen Stutzki, U. Köln

General Features

Broad coverage of the FIR and sub-mm
 Instantaneous IF bandwidth of 4 GHz
 Resolving power of up to 10^7 (0.3-300 km/s)
 Diffraction-limited (12" – 47") beam
 Seven bands utilizing low-noise dual-polarisation superconducting SIS and HEB mixers

Common Optics Light Path

The Common Optics Assembly containing seven mixer bands – five pairs of SIS mixers and two pairs of HEB (Hot Electron Bolometer) mixers, the calibration assembly, and the Local Oscillator inputs.

The Common Optics system combines seven beams and provides a beam chopper for the HIFI Instrument Modes which include: dual beam-switching, position-switching, on-the-fly mapping, frequency-switching, and cold-load switching. Dual acousto-optical (wide band - WBS) and autocorrelator (high resolution - HRS) backend spectrometers provide frequency resolutions of: 140 kHz, 280 kHz, 560 kHz (HRS), and 1.1 MHz (HRS & WBS).

HIFI sensitivity: Near-quantum noise limit sensitivity (goal < 3 hv/k)
 HIFI calibration accuracy: 10% baseline requirement; 3% goal
